“Pressure – breakdown, staging and redistribution”

Jassmine S. Safier, BSN, RN, CMSRN, CFCN
Rick Murdoch PT CWS FACCWS
Objectives

• Describe the pathophysiology of pressure ulcer formation.
• Identify patients at risk for skin breakdown. Low, Moderate, or High risk.
• Describe the methods and goals of debridement
• Describe pressure mapping.
• Describe various methods of pressure redistribution.
• Outline sitting guidelines
• Understand the Algorithm for pressure ulcer management.
Factors Influencing Ulcer Formation

• Causative forces
  – Friction
  – Shear
  – Moisture
  – Pressure
  – Time

• Methods of determining risk
  – Braden Scale
  – Norton Scale

• Interventions
  – Based on severity
  – Debridement
  – Pressure mapping
  – Pressure Redistribution
  – Sitting Guidelines
Friction

Friction is the force resisting the relative motion of solid surfaces, fluid layers, and material elements sliding against each other. There are several types of friction:

- Dry friction resists relative lateral motion of two solid surfaces in contact. Dry friction is subdivided into static friction("stiction") between non-moving surfaces, and kinetic friction between moving surfaces.
- Fluid friction describes the friction between layers of a viscous fluid that are moving relative to each other.[1][2]
- Lubricated friction is a case of fluid friction where a lubricant fluid separates two solid surfaces.[3][4][5]
- Skin friction is a component of drag, the force resisting the motion of a fluid across the surface of a body.
- Internal friction is the force resisting motion between the elements making up a solid material while it undergoes deformation.[2]
Dry Friction
Shearing force
Action in opposite directions within the same plane, but not collinear, causing one portion of an object to slide, displace, or shear with respect to another portion of the object.
Distribution of stresses inside tissue from the view of biomechanics

- Surface Pressure
- Bone
- Inside tissue
- Tensile stress
- Compression stress
- Shear stress
- Tensile stress
Maceration

Moisture-associated skin damage (MASD)

• Sources of maceration
  – Urine
  – Stool
  – Sweat
  – Wound drainage
  – Saliva
  – Mucus

• Effects of maceration
  – Local skin softening and swelling
  – Softening and swelling leads to greater susceptibility to friction and shear
  – Presence of proteolytic enzymes breaks down bonds between cells
  – Breakdown due to overaggressive cleansing or use of adhesive's
  – Exposure of more fragile deeper layers of skin tissue
  – Increase susceptibility to bacterial invasion
Maceration

Moisture-associated skin damage (MASD)
Maceration
Moisture-associated skin damage (MASD)

Normal Skin

Over Hydrated Skin

Natural Moisturizing Factor
One of the primary elements in keeping skin healthy

Comedonesomes
The "hubs" that hold the corneocytes together

Comecyte
A specialized tissue forming an external protective covering

Comified Lipid Envelope
Vital physical barrier to these tissues in mammals

Intercellular Lipids
Free fatty acids and ceramides that are released from the lamellar bodies

Lamellar Bodies
Accessory organelles found in type II granulocytes and keratinocytes

Stratum Corneum
Thin layer of cells in the epidermis

Stratum Spinosum
Layer of the epidermis found between the stratum granulosum and stratum basale
Maceration has the effect of causing breakdown of the tissues directly as well as making the tissues more venerable to other stresses. It also increases the friction coefficient which makes even mild friction more destructive.
Pressure

Under no pressure

Vessels compromised

Under pressure
The Effects of Time vs Pressure to Create an Ulcer

- Tissue Damage
- Viable Tissue

Time (Minutes)

Pressure (mmHg)

Ganz et al. (2006)
Adaptation of the Reswick-Rogers curve to show the effect of reduced tissue tolerance.

Above the line, the magnitude and duration of pressure is likely to cause pressure damage. Below the line, pressure damage is unlikely to occur.

Pressure-time curve shifts to the left and down when skin and tissue tolerance is reduced, lowering the pressure and durations required to induce pressure damage.
Figure 1. Suggested effects of the individual anatomy on the time to develop a serious pressure ulcer (PU) or deep tissue injury (DTI), based on the pressure-time injury threshold obtained in animal studies by Linder-Ganz et al. Individuals who are obese and/or have atrophied muscles are expected to develop DTI during a shorter period of time compared to persons with normal bodyweight and normal muscle thickness. Epidemiological studies indicate that an individual with spinal cord injury (SCI) is likely to gain weight and lose muscle tissue over the years post-SCI; therefore, he/she theoretically shifts from the condition of patient A to that of patient B, likely shortening the time for him/her to develop a PU or DTI under sustained loading. The seated buttocks are depicted as an example where internal tissue loads are expected to be higher than when laying down. The theory suggesting that increased bodyweight and loss of muscle mass shorten the time for DTI onset is hypothesized to hold for a supine position as well.
Pressure Ulcer

Pressure - Friction - Shear

Pressure

Shear forces and/or friction

Blood vessels collapse

Ischemia

Inflammation & Necrosis

Cell death

Pressure Ulcer

Nutritional deficiencies

Altered skin properties due to SCI

Moisture

Bacterial colonization

Infection
Cellular Effects of Pressure/Shear

- Inadequate perfusion
  - Cell hypoxia
    - Energy deficit
      - Lactic acid accumulation and fall in pH
        - Anaerobic metabolism
          - Vasoconstriction
            - Failure of pre-capillary sphincters
              - Peripheral pooling of blood
                - Metabolic acidosis
                  - Cell membrane dysfunction and failure of 'sodium pump'
                    - Intracellular lysosomes release digestive enzymes
                      - Efflux of potassium
                        - Influx of sodium and water
                          - Toxic substances enter circulation
                            - Capillary endothelium damaged
                              - Destruction, dysfunction, and cell death
### Assessment tools

## Braden Scale for Predicting Pressure Sore Risk

<table>
<thead>
<tr>
<th>Patient’s Name</th>
<th>Evaluator’s Name</th>
<th>Date of Assessment</th>
</tr>
</thead>
</table>

### Sensory Perception
- **1. Completely Limited**
  - Unresponsive (does not mean, flinch, or grasp) to painful stimuli, due to diminished level of consciousness or sedation
  - OR
  - Limited ability to feel pain over most of body

- **2. Very Limited**
  - Responds only to painful stimuli. Cannot communicate discomfort except by moaning or restlessness
  - OR
  - Has a sensory impairment which limits the ability to feel pain or discomfort over 1/3 of body

- **3. Slightly Limited**
  - Responds to verbal commands, but cannot always communicate discomfort or the need to be turned
  - OR
  - Has some sensory impairment which limits ability to feel pain or discomfort in 1 or 2 extremities

- **4. No Impairment**
  - Responds to verbal commands. Has no sensory deficit which would limit ability to feel or voice pain or discomfort

### Moisture
- **1. Constantly Moist**
  - Skin is kept moist almost constantly by perspiration, urine, etc. Dopamine is detected every time patient is moved or turned

- **2. Very Moist**
  - Skin is often, but not always moist. Linen must be changed at least once a shift

- **3. Occasionally Moist**
  - Skin is occasionally moist, requiring an extra linen change approximately once a day

- **4. Rarely Moist**
  - Skin is usually dry. Linen only requires changing at routine intervals

### Activity
- **1. Bedfast**
  - Confined to bed

- **2. Chairfast**
  - Ability to walk severely limited or non-existent. Cannot bear own weight and/or must be assisted into chair or wheelchair

- **3. Walks Occasionally**
  - Walks occasionally during day, but very short distances, with or without assistance. Spends majority of each shift in bed or chair

- **4. Walks Frequently**
  - Walks outside room at least twice a day and inside room at least once every two hours during waking hours

### Mobility
- **1. Completely Immobile**
  - Does not make even slight changes in body or extremity position without assistance

- **2. Very Limited**
  - Makes occasional slight changes in body or extremity position but unable to make frequent or significant changes independently

- **3. Slightly Limited**
  - Makes frequent though slight changes in body or extremity position independently

- **4. No Limitation**
  - Makes major and frequent changes in position without assistance

### Nutrition
- **1. Very Poor**
  - Never eats a complete meal. Rarely eats more than 1/3 of any food offered. Eats 2 servings or less of protein (meat or dairy products) per day. Takes fluids poorly. Does not take a liquid dietary supplement
  - OR
  - Is NPO and/or maintained on clear liquids or 1/4s for more than 5 days

- **2. Probably Inadequate**
  - Rarely eats a complete meal and generally eats only about 1/3 of any food offered. Protein intake includes only 3 servings of meat or dairy products per day. Occasionally will take a dietary supplement
  - OR
  - Receives less than optimum amount of liquid diet or tube feeding

- **3. Adequate**
  - Eats over half of most meals. Eats a total of 4 or more servings of meat and dairy products per day. Occasionally will refuse a meal, but will usually take a supplement when offered
  - OR
  - Is on a tube feeding or TPN regimen which probably meets most of nutritional needs

- **4. Excellent**
  - Eats most of every meal. Never refuses a meal. Usually eats a total of 4 or more servings of meat and dairy products. Occasionally eats between meals. Does not require supplementation

### Friction & Shear
- **1. Problem**
  - Requires moderate to maximum assistance in moving. Complete lifting without sliding against sheets is impossible. Frequently slides down in bed or chair, requiring frequent repositioning with maximum assistance
  - Spasticity, contractions or agitation leads to almost constant friction

- **2. Potential Problem**
  - Moves feebly or requires minimum assistance. During a move skin probably slides to some extent against sheets, chair, restraints or other devices. Maintains relatively good position in chair or bed most of the time but occasionally slides down

- **3. No Apparent Problem**
  - Moves in bed and in chair independently and has sufficient muscle strength to lift up completely during move. Maintains good position in bed or chair

## Skin Changes as we Age

<table>
<thead>
<tr>
<th>Structure</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skin</td>
<td>The skin is the largest organ of the body and is made up of three main layers: the epidermis, dermis and hypodermis. The skin has a number of very important functions; protection, sensation, thermo-regulation, secretion of sebum, sweat and cerumen and synthesis of Vitamin D. The skin is the body’s largest main protective barrier against invasive micro-organisms, toxins and UV light. It also protects the internal tissues and organs and helps maintain hemostasis. The average thickness of the skin is 1-2 mm and this varies according to anatomical site.</td>
</tr>
<tr>
<td>Epidermis</td>
<td>The epidermis is very thin: approximately 0.1 mm. It receives oxygen and nutrients via the dermis as the epidermis does not have its own blood supply. The epidermis is firmly attached to the dermis at the demo-epidermal junction. As skin ages the epidermis gradually thins, particularly after the age of 70 with a flattening interface between the epidermis and the dermis. This reduces its resistance to shearing forces. Finning makes the skin more susceptible to the mechanical forces such as friction and shear.</td>
</tr>
<tr>
<td>Dermis</td>
<td>The dermis is composed of connective tissue and other components such as blood vessels, lymphatics, macrophages, endothelial cells and fibroblasts. A reduction in collagen and elastin makes it more susceptible to friction and shearing forces. During the aging process there’s approximately 20% loss in the thickness of the dermal layer. This thinning of the dermis also causes a reduction in the blood supply to the area as well as reduction in the number of nerve endings and collagen. This in turn leads to a decrease in sensation, temperature control, rigidity and moisture control.</td>
</tr>
<tr>
<td>Hypodermis</td>
<td>The subcutaneous layer or hypodermis lies below the dermis. This layer is made of adipose tissue and connective tissue. As skin loses its elasticity and strength, its protective function is reduced. Alterations in the vascularity and thickness of the hypodermis with advanced age contributes to the skin susceptibility to trauma. In addition, the vascular capillaries become more fragile which can lead to vascular lesions such as ecchymosis (bruising) and senile purpura.</td>
</tr>
</tbody>
</table>
